1 Modeling of the P2P service migration problem

We suppose there are M videos, and N ISPs. There are one on-premise server and one cloud node in each ISP.

1.1 Main difficulty I faced

Can not merge the content placement and schedule in a framework

1.2 Optimization of the problem with Lyapunov optimization

This is a combination of optimization for one time deployment and time-average variables. The placement of content is one time deployment while the schedule is for time-average.

Notation definition:

B_s: storage capacity of the on-premise server

B_u: upload bandwidth capacity of the on-premise server

h_j: charging rate for storage on the cloud at the $j-th$ ISP

k_j: charging rate for upload bandwidth on the cloud at the $j-th$ ISP

s_m: storage of $m-th$ video

$x_m^j = \{0,1\}, m = 1,...,M$: $x_m^j = 1$ if the placement of the $m-th$ video is on the on-premise server at the $j-th$ ISP; $x_m^j = 0$ otherwise;

$y_m^j = \{0,1\}, m = 1,...,M$: $y_m^j = 1$ if the placement of the $m-th$ video is on the cloud at the $j-th$ ISP; $y_m^j = 0$ otherwise;

D_s^{ji} is the delay from source j to on premise server i, and D_c^{ji} is the delay from source j to on cloud node i.

$A_m^j(t)$: at time slot t, number of requests of the $m-th$ video generated from the $j-th$ ISP.

$r_m^j(t)$: at time slot t, number of requests of the $m-th$ video that are admitted into the system. $r_m^j(t) \leq A_m^j(t)$

$S_m^j(t)$: at time slot t, number of requests for video m that are routed from region j to on-premise server i

$C_m^{ji}(t)$: at time slot t, number of requests for video m that are routed from region j to cloud node i

$Q_m^j(t)$: at time slot t, queues of requests from video m from ISP j.

Note: The queue update is: $Q_m^j(t+1) = \max[Q_m^j(t) + r_m^j(t) - S_m^j(t) - \sum_{i=1}^{N} C_m^{ji}(t), 0]$

Different from the previous sub section, $S_m^j(t)$ and $C_m^{ji}(t)$ is not a schedule of fraction of arrival rates for all time slots. Now they are schedule of number of requests (integers) for each time slot.

Note: minimize sum of:

- time average spending cost of upload bandwidth at cloud node
- spending cost of time average upload bandwidth at on premise server
- cost of storage at cloud
- cost of storage at on premise server
- time average weighted delay

maximize $g(\sum_{m=1}^{N}\sum_{j=1}^{N}\overline{r_m^j(t)}) - \alpha_1 \overline{\sum_{m=1}^{M}\sum_{j=1}^{N}\sum_{i=1}^{N}(s_m C_m^{ji}(t) k_i)} - \alpha_2 \sum_{m=1}^{M}\sum_{j=1}^{N}\sum_{i=1}^{N}\overline{s_m S_m^j(t)} - \alpha_3 \sum_{j=1}^{N}\sum_{i=1}^{N}\overline{\sum_{m=1}^{M} s_m (C_m^{ji}(t) D_c^{ji} + S_m^{ji}(t) D_s^{ji})}$

subject to:

$0 \leq C_m^{ji}(t) \leq C_m^{ji}(t) y_m^t, \forall j = 1,..,N, \forall i = 1,...,N, \forall m = 1,...,N, \forall t$

$\sum_{m=1}^{M}\sum_{j=1}^{N} s_m S_m^j(t) \leq B_u, \forall i = 1,...,N, \forall t$ (on-premise server's upload bandwidth constraint)

Queues $Q_m^j(t)$ is stable, $\forall m, j$, i.e., $\overline{r_m^j(t)} \leq \overline{\sum_{i=1}^{N} S_m^j + \sum_{i=1}^{N} C_m^{ji}}$

$Q_m^j(0) = 0, \forall m, j$

$r_m^j(t) < A_m^j(t)$

Note:

known values: B_u, k_j, s_m, $A_m^j(t)$, D_c^{ji}, D_s^j, y_m^j

optimization variables: $S_m^j(t)$, $C_m^{ji}(t)$, $r_m^j(t)$

$\Delta(Q(t)) - Vutility$

$\leq B + \sum_{m,j} Q_m^j(t)(r_m^j(t) - S_m^j(t) - \sum_{i=1}^{N} C_m^{ji}(t)) - Vg(\sum_{m,j} r_m^j(t)) + V(\alpha_1 \sum_{m,j,i} s_m C_m^{ji}(t) k_i + \sum_{m,j} \alpha_2 s_m S_m^j(t) + \sum_{m,j,i} \alpha_3 s_m C_m^{ji}(t) D_c^{ji} + \sum_{m,j} \alpha_3 s_m S_m^j(t) D_s^j)$

$= B - \sum_{m,j,i} C_m^{ji}(t)(Q_m^j(t) - \alpha_1 V s_m k_i - V\alpha_3 s_m D_c^{ji}) - \sum_{m,j} S_m^j(t)(Q_m^j(t) - V\alpha_2 s_m - V\alpha_3 s_m D_s^j) - [Vg(\sum_{m,j} r_m^j(t)) - \sum_{m,j} r_m^j(t) Q_m^j(t)]$

2 Possible Extension

1. Add time average budget constraint
2. add the constraint of delay
